

## A slightly better analysis

$e = (u, v)$  is added s.t

$\text{Comp}(u) \neq \text{comp}(v)$       Additional store  
 $\text{Size}(u) + \text{Size}(v)$

if  $\text{Size}(u) > \text{Size}(v)$

$\text{Size}'(u) = \text{Size}(u) - \text{Size}(u) + \text{Size}(v) \geq 2\text{Size}(u)$  { Perform DFS on  $\text{cc}(v)$  and  
 $\forall w \in \text{cc}(v)$  change  $\text{comp}(w) = \text{comp}(u)$

else

Perform DFS on  $\text{cc}(u)$  &

$\forall w \in \text{cc}(u)$ , change  $\text{comp}(w) = \text{comp}(v)$

**Amortized analysis:** Instead of upper bounding the cost of each operation with the worst-case bound, bound the cost of a sequence of operations

Observation: Each time the label of a vertex changes, it moves to a component with size at least twice the old size.

Running time:  $O(\sum_{u \in V} \# \text{ of label changes of } u)$   
 $= O(V \log V) + O(E) \rightarrow \text{checking } \text{comp}(u) = \text{comp}(v)$

# Data structures for disjoint sets

Maintain a collection of sets supporting the following operations

- ①  $\text{Makeset}(u)$  - Create a set  $\{u\}$
- ②  $\text{Find}(u)$  - find the id of the set containing  $u$
- ③  $\text{Union}(u, v)$  - Compute the union of the sets containing  $u$  &  $v$

## Up-trees

- Sets represented as rooted directed trees
- Node points to its parent
- Root is the id of the set

$$F_1 = \{u_1, u_2, u_3\}$$

$$F_2 = \{v_1, v_2, v_3, v_4, v_5\}$$

Find( $u$ ): Trace the path to the root

Union( $u, v$ ): Make one root the child of the other

\* Complexity of Find - depends on the depth of the tree

Union-by-rank

rank( $u$ ) - height of the subtree rooted at  $u$

Union( $u, v$ ): If  $\text{rank}(\text{Find}(u)) > \text{rank}(\text{Find}(v))$   
rank of all  $\leftarrow$  then make  $u$  the parent of  $v$   
the nodes remain unchanged

else make  $v$  the parent  
of  $u$ .

↳ rank of the root increases  
by 1

- Union( $u_1, u_4$ ), Union( $u_2, u_5$ ), Union( $u_3, u_6$ )
- Union( $u_3, u_7$ )
- Union( $u_1, u_2$ )
- Union( $u_7, u_5$ )

① For any node  $u$   $\text{rank}(u) < \underbrace{\text{rank}(\text{parent}(u))}_{\text{depth of the subtree}}$

② For any node  $u$  of rank  $k$ , there are at least  $2^k$  nodes in its subtree

## Proof by induction

- ③ If there are  $n$  elements in total, then there are at most  $n/2^k$  elements of rank  $k$
- Subtrees are disjoint
  - Each subtree contains  $\geq 2^k$  nodes

Corollary: The highest possible rank =  $\log n$

Running time:  $O(E \log V)$  for Kruskal  
using up trees
